ABSTRACT

A frequency multiplier with active linearly tapered slot antennas (LTSA) has been demonstrated at the second harmonic frequency. In each antenna element, a GaAs monolithic microwave integrated circuit (MMIC) distributed amplifier is integrated with two LTSA. The multiplier has a very wide bandwidth and large dynamic range. The fundamental-to-second harmonic conversion efficiency is 8.1 percent. The spatially combined second harmonic signal is 50 dB above the noise level. The design is suitable for constructing a large array using monolithic integration techniques.

INTRODUCTION

The power output of solid state devices decreases as the frequency of operation increases. Hence to obtain high power at millimeter wave frequencies, the power outputs from several devices, such as, IMPATT diodes, Gunn diodes, MESFETs or HEMTs, have to be combined using either conventional power combiners or quasi-optical power combiners (1). The quasi-optical power combining techniques that have been reported include spatial amplifiers, such as grid amplifiers using MESFETs (2), spatial frequency multipliers using varactor diodes (3), and harmonic combiners using FETs (4). Quasi-optical power combiners have higher combining efficiencies over conventional power combiners because of lower conductor losses and larger dimensional tolerances with the absence of resonant waveguide cavities. In addition, integrating both antennas and devices on a single semiconductor wafer simplifies the array construction.

This paper presents for the first time frequency multiplication and space power combining with an GaAs monolithic microwave integrated circuit (MMIC) distributed amplifier and an array antenna. In this approach an array of LTSA (5) and GaAs MMIC distributed amplifiers (6) receives signal at a fundamental frequency, and after multiplication and amplification, radiates the second harmonic signal into free space. The advantages of using a distributed amplifier are a very large gain-bandwidth product and good input and output impedance match at both the fundamental frequency and the harmonic frequencies, and the advantages of using a LTSA are wide bandwidth, high gain and simple construction. In addition, unlike spatial oscillator array, the spatial multiplier array does not require injection locking for coherence and stability. However, it does require a high power source at the fundamental frequency for good conversion efficiency.

SPATIAL ACTIVE MULTIPLIER FABRICATION AND CHARACTERISTICS

The experimental three-element active array module is shown in Fig. 1. The array elements are constructed by integrating a GaAs MMIC distributed amplifier between two nonplanar LTSA.

GaAs MMIC Distributed Amplifier

The GaAs MMIC distributed amplifier was developed by Texas Instruments for NASA Lewis Research Center (6). A photograph of the amplifier chip is shown in Fig. 2. The MMIC consists of six 300 μm wide by 0.5 μm long MESFETs and is 1.25 mm x 2.63 mm x 0.1 mm. The bias network is

incorporated on the chip. The amplifier typically has a linear gain of 5 ± 1 dB over the frequency range of 2 to 22 GHz with a power output of 0.5 W under large signal operation (Drain voltage $V_d = 5.0$ V, Drain Current $I_d = 570$ mA, and Gate voltage $V_g = 0$ V). The power added efficiency at 0.5 W is 14 percent (6).

Linearly Tapered Slot Antenna

The feed system of the nonplanar LTSA consists of a conventional microstrip with the ground plane tapered to form a balanced microstrip. The strip conductors of the balanced microstrip are gradually flared with respect to the antenna axis to form the nonplanar LTSA (5). A photograph of the nonplanar LTSA is shown in Fig. 3. The antenna fabricated on a 0.508 mm RT-5880 Duroid substrate ($\epsilon_r = 2.2$) has a measured gain of 11 dB at 20 GHz and return loss of better than 10 dB over the frequency range of 10 to 30 GHz.

EXPERIMENTAL RESULTS AND DISCUSSIONS

Experimental Set-up

A simple phased locked measurement setup has been developed to measure the second harmonic generated by the spatial multiplier. In the test setup which is shown in Fig. 1, the LTSAs at the input terminals are space-fed from a X-Band waveguide horn antenna while those at the output terminals radiate into free space. The free space radiation is picked up by a K-Band waveguide horn antenna which is placed at a far field distance from the array. To establish good isolation between the transmitting and receiving horn antennas, the two horn antennas are orthogonally polarized but the LTSAs are oriented to have the same polarization as their respective horn antennas. In addition, the waveguide feed dimensions of the receiving horn antenna are such that the transmitting frequency is far below cutoff. The signal received by the second horn antenna is fed to a balanced mixer which is followed by a narrow band IF amplifier. The local oscillator (LO) of the mixer is phased locked to the transmitting oscillator resulting in good signal-to-noise ratio and also elimination of spurious responses.

Second Harmonic Generation

The amplifiers were characterized before being inserted into the array. The conversion efficiency, η , of the fundamental frequency (f_0)-to-second harmonic frequency ($2f_0$) was determined from the measurements of the power output, P_{out} , at $2f_0$ and the power input to the amplifier, P_{in} , at f_0 . Experimentally it was observed that when the amplifier was biased in the nonlinear region ($V_d \approx 2.15$ V, $V_g \approx 0$ V), the P_{out} at $2f_0$ was a maximum. This is because at $V_g \approx 0$ V, the input signal drives the gate of the MESFET into forward

conduction and hence the gate capacitance and the transconductance varies nonlinearly with the gate voltage. These nonlinear elements generate the second harmonic signal. The drain bias in each of the three MMICs was adjusted to produce a coherent output. Figure 4 shows the measured P_{out} as a function of f_0 at a fixed P_{in} of 0 dBm. The relatively constant P_{out} at $2f_0$ over the input frequency (f_0) range of 2 to 10 GHz demonstrates the wide-band characteristics of the multiplier. P_{out} is a maximum at about $f_0 = 9.3$ GHz. Figure 5 shows the measured P_{out} as a function of P_{in} at a fixed frequency of 9.3 GHz. The results that P_{out} increases from about -40 dBm to 0 dBm as P_{in} increases from -10 dBm to 10 dBm demonstrate the wide dynamic range of the multiplier. The maximum η is about 8.1 percent which occurs when $P_{in} = 10$ dBm. The above measurements were carried out using a HP 8672A Synthesized Signal generator and a HP 8566B Spectrum Analyzer.

Spatial Combining

To demonstrate spatial combining, the LTSAs at the amplifier input were excited at f_0 and the amplified $2f_0$ signal radiated from the array was received by the horn antenna. The measured E- and H-Plane radiation pattern of the horn antenna at $2f_0$ with the amplifier turned ON is shown in Fig. 6. Also shown is the noise pattern when the amplifier is turned OFF. The $2f_0$ signal is 50 dB above the noise.

CONCLUSIONS

A wide bandwidth and large dynamic range spatial frequency multiplier with GaAs distributed amplifiers and LTSAs has been demonstrated. The maximum is about 8.1 percent. The amplitude of the $2f_0$ signal is 50 dB above the noise level.
